

c. Update inventory & alert shortages

USE
CASE

Textual Description

The Inventory Manager updates the stock level of a product. The system automatically evaluates the new quantity against the defined minimum threshold. If a shortage is detected, a low stock alert is generated to trigger a resupply.

List of Actors

Inventory Manager

Pre-conditions

- The product exists in the Inventory database.
- A minimum stock threshold is defined for this product.

Post-conditions

The product's stock quantity is updated. If the quantity dropped below the minimum threshold, a new LowStockAlert is generated and persistently saved.

Main Success Scenario

1. The Inventory Manager inputs a Product ID and its new stock quantity.
2. The system retrieves the Product from the inventory database.
3. The system updates the product's current stock level.
4. The system compares the new stock level against the product's minimum threshold.
5. The system determines the stock is below the threshold.
6. The system automatically generates a LowStockAlert for the missing amount.

7. The system saves both the updated product state and the alert persistently.
8. The system displays a confirmation message.

Alternatives / Extensions

5a. Stock level is above the minimum threshold:

1. The system determines the new stock is sufficient and no shortage alert is required.
2. The system skips the alert generation step.
3. Proceed to step 7 (saving only the updated product state).
